

## Chapter 3

---

### 1 Connectedness

#### 1.1 Connectedness

**Definition:** A space  $X$  is connected if it cannot be the union of two disjoint non empty open sets.

**Theorem:** The 3 statements are equivalent

- A space  $X$  is connected.
- $X$  cannot be the union of 2 disjoint non empty closed sets.
- The only subsets of  $X$  that are both open and closed are  $X$  and  $\emptyset$ .

**Corollary:** If  $A$  is connected in a topological space  $X$  and  $A \subset \mathcal{U}_1 \cup \mathcal{U}_2$  where  $\mathcal{U}_1$  and  $\mathcal{U}_2$  are 2 disjoint open sets then  $A$  is entirely included in one of the open sets.

**Theorem:** The union of a collection of connected subspaces that have a point in common is connected.

**Theorem:** Given a connected subset  $A$  of a topological space  $X$ , If  $B$  satisfies  $A \subset B \subset \bar{A}$  then  $B$  is connected

**Corollary:** If  $A$  is connected, then the closure  $\bar{A}$  is connected.

**Theorem:** The image of a connected space under a continuous function is connected.

**Theorem:** A finite Cartesian product of connected spaces is connected.

**Definition:** Given a set  $Y$  and a total order relation on  $Y$ , the order topology is generated by the intervals  $(x, y) = \{z \in Y : x < z < y\}$

**Theorem (intermediate value):** Let  $f : X \rightarrow Y$  a continuous function from a connected space  $X$  to a totally ordered space  $Y$ . Then for any two point  $a$  and  $b$  in  $X$ , and for any value  $r \in Y$  between  $f(a)$  and  $f(b)$ , there exists  $c$  in  $X$  such that  $f(c) = r$ .

## 1.2 Path connected

**Definition:** A set  $A$  is path connected if for any 2 points  $a$  and  $b$  in  $A$ , there exists a path entirely included in  $A$ ,  $c : [0, 1] \rightarrow A$ , such that  $c(0) = a$  and  $c(1) = b$ .

**Theorem:** If  $A$  is path connected, then  $A$  is connected.

**Example:** The set  $\bar{G} = \left\{ \left( x, \sin \left( \frac{1}{x} \right) \right) \in \mathbb{R}^2, x \in (0, 1] \right\} \cup \{0\} \times [-1, 1]$  is connected and not path connected.

## 2 Compactness

### 2.1 Compactness

**Definition:** Let  $X$  be a topological space.  
A cover of  $X$  is a collection  $\mathcal{A}$  of subsets of  $X$  such that  $X = \bigcup_{A \in \mathcal{A}} A$ .  
A subcover  $\mathcal{B}$  of  $X$  is a subset of  $\mathcal{A}$  that covers  $X$ , i.e.  $X = \bigcup_{A \in \mathcal{B}} A$ .

**Definition:** A set  $C$  in a topological space  $X$  is compact if for any cover of  $C$  with open sets, there is a finite subcover of  $C$ .

**Example:**

- $[0, 1]$  is compact
- If  $x_n$  is a convergent sequence and  $x$  is its limit, then  $S = \{x, x_n, n \in \mathbb{N}\}$  is compact.

**Theorem:** Every closed set of a compact set is compact.

**Theorem:** The compact sets of  $\mathbb{R}$  are the closed and bounded sets.

**Theorem:** If  $X$  be a compact topological space, and  $f$  be a continuous function from  $X$  to  $Y$  then  $f(X)$  is compact.

**Theorem:** If  $f$  is a continuous function from a compact set  $X$  to  $\mathbb{R}$ , then for any  $a$  and  $b$  in  $X$ , there exists  $c$  in  $X$  such that  $f(c)$  is between  $f(a)$  and  $f(b)$ .

**Theorem:** The product of finitely many compacts is compact.

**Remark:** The theorem is also true for an arbitrary product. It won't be proved in class.

**Definition:** If  $(X, d)$  is a metric space,  $A$  is a non empty subset of  $X$ , and  $x$  an element of  $X$ , the distance between  $x$  and  $A$  is defined by

$$d(x, A) = \inf(d(x, a), \forall a \in A)$$

**Remark:**

- $d(x, A)$  is a continuous function of  $x$ .
- $d(x, A) = 0$  iff  $x \in \bar{A}$

**Theorem:** Let  $\mathcal{A}$  be a cover by open sets of a metric space  $X$ . If  $X$  is compact, there exists a positive number  $\delta$  such that any ball with diameter  $\delta$  is entirely included in an element of  $\mathcal{A}$ .

**Theorem:** If  $f$  is continuous from  $(X, d_X)$  a compact metric space to  $(Y, d_Y)$  a metric space, then  $f$  is uniformly continuous.

## 2.2 Hausdorff Space

**Definition:** (page 88) A topological space  $X$  is Hausdorff space if for any  $x_1 \neq x_2$ , there exists 2 disjoint open sets  $\mathcal{U}_1$  and  $\mathcal{U}_2$  such that  $\mathcal{U}_1$  contains  $x$  and  $\mathcal{U}_2$  contains  $y$ .

**Theorem:** If  $X$  is Hausdorff, any sequence has at most one limit point.

**Definition:** The order topology on  $X$  is generated by the open sets

- $(a, b)$  for any  $a, b$  in  $X$ .
- $[a_0, b)$  for any  $b$  in  $X$  and  $a_0$  being a smallest element of  $X$
- $(a, b_0]$  for any  $b$  in  $X$  and  $b_0$  is the greatest element of  $X$

**Theorem:**

- A totally ordered space is Hausdorff for the order topology.
- The product of 2 Hausdorff space is Hausdorff.
- A subspace of a Hausdorff space is Hausdorff.
- Metric spaces are Hausdorff
- $\mathbb{R}^n$  is Hausdorff.

**Theorem:** Any compact space of a Hausdorff set is closed.

**Theorem:** Let  $f : X \rightarrow Y$  be a continuous function. If  $X$  is compact and  $Y$  is Hausdorff, then  $f$  is an homeomorphism.

**Theorem:** Let  $X$  be a non empty compact Hausdorff space, if  $X$  has no isolated point, then  $X$  is non countable.
